#### ACKNOWLEDGEMENT

It is quite legitimate to express that the credit of this work is shared by many individuals. First and foremost the authors want to express their profound gratitude and indebtedness to Professor Syed Nawab Haider Naqvi, Director of the Pakistan Institute of Development Economics, for his encouragement, help, guidance and patience. Without his support and blessings, this study could not have been completed. We are also grateful to Dr. Von Endel, Dr. Ghulam Rasool, Dr. A. R. Kemal and Dr. Nasir M. Khilji, for their comments which helped to improve the quality of our effort.

We wish to express our thanks to Syed Hamid Hasan Naqavi, the literary Editor to the *Pakistan Development Review*, who provided excellent editorial assistance in preparing the manuscript. Finally, we feel obliged to our many colleagues who contributed directly or indirectly to the preparation of the final draft.

## INPUT-OUTPUT TABLES OF PAKISTAN'S ECONOMY: 1975-76

Input-output tables not only provide a consistent accounting framework, they are also very useful for analytical purposes. By tracing out the inter-industry flows in which sector a commodity is produced and how it is consumed in various sectors of the economy an input-output table summarises the interdependence of the various sectors of the economy. Since such tables supply detailed information on estimates of outputs, inputs and the value added in each sector of the economy, they provide a check on National Accounts data as well.

Input-output tables are of basic importance to any planning exercise. In development plans, targets of final demand and gross output of various products are generally marked. However, these targets of gross output may not be necessarily consistent with those of the final demand. Moreover, production plans, being subject to the given resource constraints may not even be feasible. The input-output table evaluates the consistency of the various targets by computing the required levels of gross output in different sectors of the economy corresponding to the given levels of final demand. It also explores the feasibility of such production plans by computing the required labour of various skills, capital, etc. corresponding to the gross level of production.

Input-output tables are not only relevant to evaluating the consistency and feasibility of various development plans they are also quite useful in multi-sector optimisation models as they provide necessary data for constraints formulation. Some other important applications relating to input-output tables are: Projections of demand, output, employment and investment for different sectors of the economy, the overall factor intensities of imports and exports and net foreign exchange earnings or savings through exporting or import-substituting a product, analysis of the effects of wages, profits and tax changes, prices, development planning, etc.

Input-output tables have a fairly long history in Pakistan and date back to 1962, when the first input-output table was formulated by Fei [3]. The table related to input structures of only agriculture, mining and large-scale manufacturing sectors. The construction and services sectors were altogether ignored. Obviously, Fei's table was not very comprehensive from analytical standpoint.

The first comprehensive input-output table in Pakistan was prepared by Rasul and related to the year 1954 [24]. The table comprised transaction flows for 71 products corresponding to the cost structure of 27 productive sectors. Following Rasul, a  $40 \times 40$  inter-industry transaction flow matrix relating to the year

1959-60 was prepared by Ahmad (1), a 30 x 30 inter-industry flow table relating to the calendar year 1960 was prepared by Norbye (6), a 30 x 30 table for the year 1960-61 was prepared by Tims (31), and a 54 x 54 inter-industry flow matrix for 1963-64 was prepared by Tims and Stern (15)<sup>1</sup>. However, all these tables related to Pakistan as a whole which included East Pakistan also. Nevertheless, three other tables were also prepared for West Pakistan: Rasul's table consisting of 70 sectors and relating to the year 1962-63 [27], Khan and MacEwan's<sup>2</sup> table for 1962-63 consisting of 35 sectors [4], and Rasul and Jarret's table relating to 1968-69 consisting of 21 sectors [26]. We may point out that while all these input-output studies, related to either the mid-Sixties or late Sixties, no efforts have hitherto been made to construct a table for the Seventies. Since input-output coefficients change significantly over time, tables relating to the Sixties if applied to the present conditions, may yield altogether misleading results. Hence, the policy makers in general and researchers, in particular have been handicapped in policy formulation and economic analysis owing to non-availability of an input-output table for a more recent year.

1. For detailed references of studies on input-output tables, see Rasul (27).
2. Khan and MacEwan prepared the table drawing heavily on Rasul's table. They felt that Rasul's table was lop-sided wherein three fourths of the sectors corresponded to the large-scale manufacturing sector which contributed only 12 percent to the gross national product.

The input-output table presented here relates to the year 1975/76 - the most recent year for which data are available to bridge this important gap.

The plan of the study is as follows. The basic accounting framework and valuation of the transactions are discussed in the first section. The second section is devoted to sector classification. The availability of data required for the formulation of input-output table is discussed in the third section. The inter-sectoral transfers of inputs and outputs in the case of joint-product firms and the imputation procedures adopted in this context are also detailed in the third section. Improvements of the revised version over the preliminary report are discussed in the fourth section. The procedure followed to disintegrate the final demand vector into its various components is also outlined in the fourth section. Finally, limitations of data, possibilities of extending the coverage and suggestions for improving the table are discussed in the fifth section. The inter-industry flow matrix, final demand vectors and I-O coefficients matrix are reported in the Statistical Annexure.

I. Accounting Framework and Valuation of Transaction

a) Accounting Framework:

The following standard input-output accounting framework has been employed to study the inter-industry flow which consists of two balanced equations. The equation for domestic products is as follows.

$$X_i = \sum_j X_{ij} + C_i^d + I_i^d + S_i^d + E_i$$

where

$X_i$  = Production in the  $i$ th activity;

$X_{ij}$  =  $i$ th indigenous input being consumed in the sector;

$C_i^d$  = Final consumption of the  $i$ th indigenous product;

$I_i^d$  = Use of the  $i$ th indigenous product as investment;

$S_i^d$  = Changes in stock of  $i$ th indigenous product; and

$E_i$  = Export of the  $i$ th product.

The equation for imported products is

$$M_i = \sum_j M_{ij} + C_i^m + I_i^m + S_i^m + RE$$

where

$M_i$  = Import of the  $i$ th product;

$M_{ij}$  =  $i$ th imported input being consumed in the sector;

$C_i^m$  = Final consumption of the  $i$ th imported product;

$I_i^m$  = Use of the  $i$ th imported product as investment;

$S_i^m$  = Change in stock of the  $i$ th imported product; and

RE = Re-export of the  $i$ th product.

Obviously, there will be two separate input-output coefficient matrices, namely domestic coefficient matrix and trade coefficient matrix.

b) Valuation of Transactions

Input-output tables may be formulated either at producers' prices or at purchasers' prices.

The inter-industry transactions valued at producer's prices imply that transport costs and trade margins on the purchase of inputs are paid by the users of inputs and, as such, these two inputs appear as separate costs in the activity, whereas the valuation of transactions at purchaser's prices implies that each activity bears the trade and transport costs on sales of its output. Therefore, the trade and transport costs incurred on the sale of output appear as inputs going into the activity. Although for valuating inter-industry transactions the notion of producer's prices is superior to that of

purchasers' prices as it corresponds better with the input-output accounting framework, yet the transactions are frequently recorded at purchasers' prices due to data limitations.<sup>1</sup> It may be noted that various surveys and censuses generally report data on cost of inputs at purchasers' prices and the appropriation for trade and transport costs, necessary for converting values at purchasers' prices to those at producers' price is going to be rather arbitrary. For example, data relating to inputs in the census of manufacturing industries of Pakistan are recorded at purchasers' prices.<sup>2</sup> Similarly, costs of inputs in small-scale industries and other sectors are also recorded at purchasers' price.<sup>3</sup> Therefore, the system of purchasers' prices is employed in the input-output table presented in this study.

The value of output at producers' prices has been adjusted for trade and transport costs in order to bring it at purchasers' prices. While the f.o.b. values of exports and re-exports are assumed to be the values at purchasers' prices as they include transportation cost and trade margins, the c.i.f. value of imports is appropriated for the import duty, sales taxes, trade margins and transport costs in order to arrive at the value of imports at purchasers' prices.

The point need not be laboured that a finer disaggregation of production activities is more relevant in the analytical content. However, the availability of data defines its own limits to the extent of disaggregation. Since the quality and magnitude of data varies significantly across various sectors of the economy, the table will be lop-sided if disaggregation is merely governed by data availability. Therefore, we must devise some criteria which bring into sharp focus the important links in the economy. The sector classification in this study has been carried out on the basis of the criterion that various products covered in a sector should be homogeneous and bear a similar cost structure. On the basis of this criterion and under the data availability constraint, 118 sectors have been identified which are distributed over various broad groups of activities as follows: 15 in agriculture, 1 in mining and quarrying, 51 in large-scale manufacturing, 30 in small-scale manufacturing, 7 in construction and 14 in services. We shall briefly discuss in the following the rationale of the sector classification we have adopted in this study.

Agriculture has been distinguished into twelve crop sector and three non-crop sectors. The twelve crop sub-sectors are wheat growing on small farms, wheat growing on large farms, rice growing on small farms, rice growing on large farms, cotton growing on small farms, cotton growing on large farms, sugar-cane growing on small farms, sugar-cane growing on large farms, tobacco growing, oil seeds other than cotton seeds, pulses and other crops. Three non-crop sectors are: Livestock, fishing and forestry. Small and large farm activities of wheat, rice, cotton and sugar-cane are distinguished as they differ significantly in their cost structures in these two types of activities<sup>3</sup>. However, the data constraints did not permit us to distinguish tobacco, oil seeds, pulses and other crops between small and large farm activities.

3. Farm sizes upto 12.5 acres are classified as small and more than 12.5 acre classified as large farms. 12.5 acres was taken as the deviding line because: (i) This is taken as the subsistence level of holding; and (ii) Inter-size variations in input structure and for productivity were significant when 12.5 acres is taken as the deviding line.

Fifty-one large-scale manufacturing activities have been distinguished. The share and potential of various sectors in output and for exports have been the binding rule in defining sector classification of various activities. Unfortunately, we could not distinguish between cigarette manufacturing, tobacco redrying and stemming activities because the data on both the industries showed that the two activities were highly integrated and as such transferring of outputs and inputs from one sector to another would have been quite arbitrary. Similarly, wood and furniture activities have been left integrated in one sector.

The small-scale manufacturing sector was not given its due importance in previous studies on input-output tables of Pakistan. Small-scale manufacturing activities were either lumped with the large-scale manufacturing activities, as in Khan and MacEwan [4] or all the small-scale manufacturing activities were combined together in one sector, as in Rasul [27]. Since it is widely believed that small- and large-scale activities differ significantly in their respective efficiencies, it would not be very wise to aggregate small- and large-scale activities. Moreover, small-scale activities bear significantly different cost structures among themselves and as such integrating all those activities into one sector is absurd. In the

present study, thirty small-scale manufacturing sectors have been identified to capture differences in small- and large-scale activities.

Seven activities have been distinguished in the construction sector. There are six urban construction activities and one rural construction activity. The urban construction activities include low-cost residential buildings, luxurious residential buildings, factory buildings, public buildings, roads and other infrastructures.

Fourteen service sectors have been identified in this study. Electricity and gas have been classified as separate activities (which were lumped together in the previous tables) as they differ in the nature of the service they provide and bear significantly different cost structures. Similarly, four different types of transport activities are identified, viz. road, rail, air and water transport. Three communication activities viz. television, radio and telephone, telegraph and post have been distinguished because of the differences in the nature of output as well as structure of inputs. Details of the sector classification are given below.

AGRICULTURE: CROP SECTORS

Code No.

- 001      Wheat Growing on Small Farms
- 002      Wheat Growing on Large Farms
- 003      Rice Growing on Small Farms
- 004      Rice Growing on Large Farms
- 005      Cotton Growing on Small Farms
- 006      Cotton Growing on Large Farms
- 007      Sugar-cane Growing on Small Farms
- 008      Sugar-Cane Growing on Large Farms
- 009      Tobacco Growing
- 010      Oilseeds other than Cotton Seeds
- 011      Pulses
- 012      Other Crops

AGRICULTURE: NON-CROP SECTORS

- 013      Livestock
- 014      Fishing
- 015      Forestry

MINING AND QUARRYING

- 016      Mining and Quarrying

LARGE-SCALE MANUFACTURING INDUSTRIES

- 017      Grain Milling
- 018      Rice Milling

- 019 Sugar Refining
- 020 Edible Oils
- 021 Tea Blending
- 022 Fish and Fish Preparations
- 023 Confectionery and Bakery
- 024 Other Food Industries
- 025 Beverages
- 026 Cigarettes and other Tobacco Products
- 027 Cotton Yarn
- 028 Cotton Fabrics
- 029 Silk and Synthetic Textiles
- 030 Woollen Textiles
- 031 Hosiery
- 032 Thread Ball Making
- 033 Carpets and Rugs
- 034 Other Textiles
- 035 Footwear Other Than Rubber Footwear
- 036 Wearing Apparel
- 037 Wood, Cork and Furniture
- 038 Paper, Paper Board and Paper Products
- 039 Printing and Publishing
- 040 Leather and Leather Products
- 041 Rubber Footwear
- 042 Other Rubber Products
- 043 Pharmaceutical and Medicinal Preparation
- 044 Fertilizer
- 045 Perfumes and Cosmetics

- 046 Paints and Varnishes
- 047 Soaps and Detergents
- 048 Matches
- 049 Other Chemicals
- 050 Plastic Products
- 051 Petroleum Products
- 052 Cement

140	Total Intermediate Inputs
150	Indirect Taxes less Subsidies
160	Value Added
200	Gross Value of Output

### III. ESTIMATES OF OUTPUT, INPUTS AND INTER-INDUSTRY TRANSACTIONS

In general a column-by-column approach to estimate various components of the Input-output table is employed in this study. That is, first a sector-wise analysis of the structure of inputs is carried out, and total inter-sectoral deliveries are then estimated by summing up all columns for a row. However, estimation of inputs through a row approach, by distributing total cost of these inputs over all sectors on the costs of some known or assumed proportion, is obtained wherever it is found inevitable. Banking and Transport costs are the two important inputs for which a row estimation is made. We will first discuss the distribution of these inputs over various sectors prior to sector-wise discussion of the structure of inputs.

#### Distribution of Banking and Transport Inputs

Interest payments, material costs and value added altogether form the total cost of the banking sector. Interest payments, being financial flows, are generally ignored in the input-output analysis. Total output originating in the banking sector has accordingly been taken as the sum of material costs and the value added. The deliveries of the banking sector are distributed over deposits and advances in the proportion of their respective values. These deliveries are then distributed

over various activities corresponding to the advances to various sectors of the economy, while deliveries of the banking sector corresponding to deposits have been allocated to the final demand.

As mentioned earlier, four transport activities, viz. railway, road, air and sea transports, have been identified. Data relating to railway freights paid by various activities are available from 1970. The gross value of output in transporting goods through trucks has been estimated on the basis of the value added data reported in National Accounts. Data are also required on the distance over which goods have been transported in addition to those on volume of goods so as to enable us to distribute transport costs over various activities. No such information was directly available for the year 1975-76. Per unit/kilometer cost is provided in previous input-output tables which, however, needs to be adjusted for increases in fares. Therefore, the per unit/kilometer cost in 1962-63, coupled with the gross output in various sector in 1975-76, was employed to compute relative shares of various activities in transport cost. These proportions were then used to compute transport costs for various activities. In order to arrive at road transport cost, these costs are further adjusted for the cost involved in other transport activities.

As described before, in this study we have followed an approach in which the structure of inputs for each sector has been analysed. Beginning with the agriculture sector we discuss below the procedure adopted in valuating output and inputs by sectors.

Valuation of Output and Inputs  
In Agriculture (Crop Sector)

a) Valuation of Output:

The gross value of the output of wheat, rice, cotton, sugarcane, tobacco, oilseeds, pulses and other crops is obtained from the the National Accounts of Pakistan. However, the National Accounts data do not report any information on the value of fodder which forms a major proportion of other crops; nor do they give the value of output by farm size. We now discuss the methodologies adopted in estimating the value of fodder and splitting the output of wheat, rice, cotton and sugarcane by small and large farms.

The value of fodder crops has been estimated as a product of acreage under fodder crops and the value of fodder per acre, while the acreage under fodder crops has been taken from the Economic Survey [9]. But the survey does not report the value of fodder output per acre. However, Salam [28] did provide the value of fodder for the year 1972-73, based on data yielded by the Farm Machanization Survey. After allowing for the price increase for the intervening period, the value of fodder per acre is estimated at Rs.600.

The value of output of wheat, rice, cotton, and sugarcane has been distinguished by small and large farms on the basis of sown average and per-acre

yield differences between the two types of farms. The Pakistan Economic Survey reports data on these crops. The percentage of the area under small and large farms has been computed on the basis of the data reported in the Census of Agriculture, 1972 [11]. The two sources provide us crop-wise data on acreage by farm size. Average yields per acre on the two types of farms were obtained from the WAPDA Survey,<sup>4</sup> which is also the main source of data on the input structure of the crop sector in this study. On the basis of the ratios computed from the data on area under the two sizes of farms for each crop and the average yields on the two farm sizes were employed to divide the value of output obtained from the National Accounts<sup>5</sup> into the values of output on small and large farms.

**b) Valuation of Inputs:**

The following inputs have been taken into account for the crop-sector.

1. Seeds
2. Farm-yard Manure
3. Green Manure

---

4. The WAPDA Survey, conducted for 1976-77, covered 1400 farms.

5. Data relating to the total value of output reported in the National Accounts have been given preference to those contained in the Survey due to the wider coverage of the former.

4. Fertilizer
5. Gypsum
6. Insecticides
7. Trade
8. Transport
9. Water
10. Fuel
11. Electricity
12. Maintenance of Tractors, Tubewells and Hand-tools
13. Draft Power
14. Banking

The information on per acre consumption of seed, farm-yard manure, Gypsum and insecticides for various crops were available from the WAPDA Survey. The fertilizer consumption have been obtained from NDFC Report [19]. As crop-wise fertilizer consumption is not available from any source, it has been arrived at indirectly. The acreage under various crops by farm size, along with per acre fertilizer off-take in various crops as reported in the WAPDA Survey, generated the data given in Table 6, representing the proportions in which fertilizer has been applied to various crops.

Table 6

Crop-Wise Use of Fertilizer by Farm Size  
(As percentage of total consumption)

Crops	Farm Size	Use of Fertilizer as % of Total Fertilizer Use in the Agriculture (Crop) Sector
Wheat		48.80
	Small Farms	16.43
	Large Farms	32.37
Rice		8.25
	Small Farms	3.23
	Large Farms	5.02
Cotton		15.70
	Small Farms	4.78
	Large Farms	10.92
Sugar-cane		7.56
	Small Farms	2.91
	Large Farms	4.65
Pulses		0.14
Oilseeds		0.14
Tobacco		1.65
Other Crops	Total	17.76 100.00

While the cost incurred on the use of canal water has been shown as input appearing against the government sector, the cost on tubewell water has been sliced down into cost involved in diesel oil, electricity and the maintenance of tubewells. The cost of canal water has been distributed over the agricultural activities of the crop sector on the basis of the irrigated area under each activity and the intensity of water use. The Agriculture Census 1972 reports data on irrigated area as proportion of the total area under various crops by small and large farms. These data, coupled with those on crop-wise total acreage as contained in Economic Survey, provide us with the irrigated area under various crops by farm size. This area under different crops, multiplied by water rates obtained from Chaudhary and Ashraf [2], gives the cost incurred on canal water in various agricultural activities.

Tubewells are either electricity- or diesel-operated. The cost of electricity consumed in agriculture has been obtained from WAPDA reports. Since electricity is provided at subsidised rates to the agriculture sector, the costs given in the WAPDA reports underscore its usefulness. Electricity has accordingly been appropriated for a pre-subsidy situation. Information on per acre water requirements and the acreage under different crops was employed to compute electricity consumption by crops and farm size.

The Energy Data Year Book [16] provides the cost of diesel to operate tubewells. Fuel consumption in agriculture has separately been distinguished as consumption of Light Diesel Oil which is used in running tubewells, While fuel consumption for operating tractors has been integrated with the fuel used by transport as given in the Energy Data Year Book. The information relating to the number of tractors, average use in hours per year per tractor and the average cost of diesel per tractor has been manipulated to estimate fuel consumption on tractors. The Census of Farm Mechanization [12] reports data on tractor hours operated in 1975-76, while the Farm Mechanization Committee [10] suggested the diesel consumption as 1.25 gallons per tractor hour. However, the diesel consumption per tractor hour is expected to decline over time since tractors of 45 H.P. or less formed a larger proportion as compared with that in the Sixties. Fuel consumption per tractor hour has, therefore, been assumed to be one gallon. This assumption is also supported by the few farmers who were interviewed. Cost of High Speed Diesel Oil has been assigned to various activities on the basis of acreage under different crops<sup>6</sup>. Fuel consumptions by tractors and tubewells were combined together to represent total fuel consumption in various agricultural activities.

---

6. Although ploughing may differ across various crops, no such data have been collected in Pakistan and as such it is not possible to distribute fuel costs in a more refined manner.

The data on marketed surplus in various crops and the trade margins, as obtained from the National Income Commission Report [21] and the Utilization of Agricultural Commodities [13], have been employed to arrive at trade input in different agricultural activities.

The maintenance cost of agricultural machinery has been derived from the data reported in the Farm Mechanization Report. On the basis of the number of tractors and tubewells and the average cost of maintenance, the total cost of repairs has been estimated. This cost has been then distributed over various crops in accordance with the fuel costs incurred on tubewells and tractors.

The value of draft power is assumed equal to the value of fodder crops in the National Accounts, which is not necessarily true. An attempt has, therefore, been made to impute values to both the fodder crops and the draft power. The cost per bullock taken from the Farm Budget Survey [23] and the number of draft animals obtained from the livestock census [23] have been employed to estimate the value of draft power.

The value-added estimates in the crop sector of agriculture as arrived at in this study differ from those in National Accounts because the cost involved in those inputs which have been accounted for in this study has not been deducted from the value of output in the National Accounts. Draft power is one of these inputs. On the output side, the value of fodder, which was not included in the National Accounts, has been accounted for in this study. In Table 7, the value added in agriculture as reported in this study is compared with that reported in National Accounts.

Table 7  
Value Added in Agriculture (Crop Sector)

Source of data	(Million Rs.) Value Added in the Agriculture (Crop Sector)
National Accounts	26,602
Estimates of this Study	25,320

The table shows that the value added in the agriculture (crop) sector, as estimated in the present study, is lower than that reported in National Accounts. However, as we shall see later, this is more than compensated by an increase in the value added in the non-crop sector of agriculture.

### Valuation of Output-Inputs in Livestock

The estimates of the value added in the livestock activity as given in National Accounts are based on the number of animal heads taken from the livestock census and the assumed value of output per animal head. It is further assumed that no current inputs are being consumed in this activity and as such the value added is equal to the value of output. It is worth noticing that while no current input is accounted for in the livestock, draft power is also not included in the value of its output. In this study, the value of draft power is imputed according to the methodology outlined earlier and the value of output originating in the agriculture sector has been accordingly adjusted. The other inputs in addition to the fodder crops which have been identified in the livestock sector are pharmaceuticals and medicines and mining and quarrying.

### Valuation of Output and Inputs in Fisheries

The value of output in Fisheries has been taken from the National Accounts. The cost of current inputs, viz. plastic products, trade and transports, has been estimated following the methodology described in the National Accounts.

### Valuation of Output and Inputs in Forestry

The National Accounts estimates of the value of output in forestry fell far short of what is actually originating in this sector. These estimates seem to ignore the value of the forest grazed in rural areas for purposes of construction and firewood. The estimated use of forestry products was Rs.848.5 million as against the value of output of Rs.297.2 million in the National Accounts. Therefore, the higher figure has been used. The cost structure was obtained from the Statistics of Forestry [7].

As discussed above, the value is imputed to both the fodder and draft power. Since draft power is also used in other sectors, e.g. in transport, the value added in agriculture as reported in National Accounts is under-estimated. Moreover, the estimates of forestry in our study are also higher than the ones given in National Accounts. Therefore, the value-added estimates in agriculture in the present study exceed those reported in the National Accounts. The comparison of the two sets of estimates is given in table 8.

Table 8

Comparison of Estimates of Value Added  
in Agriculture of this Study with those  
of National Accounts.

Source of Data	(Million Rs.)		
	Total	Crop Sector	Non-Crop Sector
National Accounts	38,322	26,602	11,720
Estimates of this Study	39,728	25,820	13,908

It may be noted that with the necessary adjustments made in this study for computation of the value added, the share of non-crop sector in the value added in agriculture increases from 30.6 percent to 35.0 percent.

Valuation of Output and  
Inputs in Mining and Quarrying

The value of output in mining and quarrying, as reported in the National Accounts, is significantly lower than the value of such inputs used by all sector. Therefore, the National Accounts data were adjusted for the estimates of sand and stone used in the construction activity. The estimates of inputs and the value added are derived by following the methodology indicated in the National Accounts.

by sectors.

#### Input and Output Valuations in Large-Scale Manufacturing

Any firm registered under 2j or 5i regulations, i.e. a firm employing ten or more persons, has been defined as a large-scale manufacturing firm in this study. Almost every year a census of manufacturing establishments is carried out which includes data on fixed assets, labour, output, material costs, fuel, electricity and some other costs. Although censuses do provide data on detailed input structures needed to formulate the input-output table, these data are not available even in tabulated form except for the Punjab. Therefore, to derive data on input structures relating to other three provinces, we have to rely on CMI questionnaires.

Among others, the major problem that the CMI data suffer from has been that of rather high ratio of non-response by firms to the CMI questionnaire, the non-response over a few years having gone up as high as forty percent. No comprehensive survey has so far been carried out in this context since 1959/60.<sup>7</sup>

In order to formulate an inter-industry flow matrix, we required data free of these bottlenecks. Therefore, the PIDE partially sponsored the survey on non-respondent firms to eliminate such problems in the CMI data.

---

7. Although a survey was carried out in 1963-64, it was not very extensive.

Moreover, the CMI data relating to other costs except indirect taxes, insurance and selling charges are not very reliable. The quality of data relating to other costs which include telephone, telegraph and postal costs, water charges, and other service charges could not escape grave doubts of even the Bureau of Statistics itself. Consequently, data on other costs, as reported in the Census of Manufacturing Industries have not been considered, while the data on indirect taxes, insurance and selling expenses were drawn from the CMI as these were of reasonably good quality.

Most of the manufacturing industries are joint-product industries and as such these products could not be classified in a single sector. All such industries require transfers of outputs and inputs from one activity to another. The inter-activity transfer of inputs may be carried out on the basis of either commodity technology or industry technology. The commodity technology assumes that the commodity has the same input structure irrespective of the activity in which it is being produced, while industry technology assumes that the cost structure is the same for all products in a particular activity. The commodity or industry technology has been employed to make inter-industry transfers of output and inputs in the case of joint-product industries depending upon the problem at hand.

The inputs already being valued at purchasers' prices need no adjustment, while the output as being valued at producers' prices did require adjustment for trade and transport mark-ups to

help in arriving at the value of output at purchasers' price. Trade mark-ups used in this study are those which relate to the National Accounts and are contained in the earlier input-output tables.<sup>8</sup>

The Census of Manufacturing Industries adjusted for non-response, provided us with data on output and inputs which fully account for non-response. However, in two activities, viz. Cotton-ginning and petroleum products, the estimation was based on independent data sources.

A comparison of the value added in large-scale manufacturing sector as estimated in this study with that reported in National Accounts will be of interest to data analysts, and is given in Table 3.

Table 3  
Value Added in the Large-Scale Manufacturing Sector

	(Million Rupees)
National Accounts	14,438
Our Estimates	9,056

The two sets of estimates clearly strike a surprising difference which calls for an explanation. To understand the nature of the difference between the two sets of estimates, one should know how the National Accounts estimates are prepared in Pakistan.

8. Mark-ups are expected to increase over time. As such our estimates underestimate the trade margin. These will be discussed in Section V.

Estimates of the value added in large-scale manufacturing at constant factor cost of 1959-60 are obtained by applying a quantum index of industrial production to the benchmark estimates for 1959-60. The index is based on the CBR returns and a survey conducted specially for the National Accounts. To arrive at value-added estimates at current factor cost, the data on constant factor cost are multiplied by wholesale price index for the manufacturing sector which may lead to erroneous estimates of the value added because the ratio of the value added to the value of gross output may not remain invariant. For example, this ratio has declined from 32.3 percent in 1959-60 to 24.5 percent in 1975-76. Secondly, inflating the constant factor cost data by wholesale price index does not necessarily yield data at current factor cost since price indices are also influenced by changes in indirect taxes. Therefore, both these factors would be responsible for overstating the value added reported in National Accounts. Moreover, the difference in the estimates of other 'costs' could be another factor responsible for the difference in the two sets of the value-added estimates. Other costs were assumed to be nearly Rs.63 million, which is 1.76 percent of the output, to evaluate the value added in 1959-60; on this basis the other costs worked out at 8.45 percent of the gross output at factor cost in 1975-76. The difference in the value added to the extent of Rs.2442 million in the two sets of estimates can be attributed to the differences in other costs. Since estimates of indirect taxes for 1959-60 are not available, we can not determine the extent to which the tax

increase is important in explaining this difference. The above considerations have led us to safely conclude that National Accounts grossly overstate the value added originating in the large-scale manufacturing sector.

#### Small-Scale Manufacturing Sector

The small-scale activities were either integrated with large-scale activities or lumped into a single sector in all previous input-output tables. On the other hand, thirty small-scale activities have been distinguished in the present study.

Data for small-scale activities were obtained both from the Census of Small-Scale Industries, Punjab, and the province-wise Census-Cum-Survey of Small-Scale Industries, conducted by the Statistics Division, relating to the year 1976-77 which, however, relate only to the urban areas. The following methodology has been employed to account for the rural small-scale manufacturing activities. The major rural activities, viz., rice husking, flour milling, gur making, edible oils and textiles, are identified. In the first place, the value of production in these industries has been estimated through residual method, i.e. the raw materials which have not been elsewhere consumed are used in the small-scale activities. Paddy, wheat, sugar-cane, oilseeds and cotton yarn have been identified as major inputs respectively in the activities listed above. The output and other input data were then blown up on the basis of the major input ratios.

Data on input structures in the small-scale manufacturing like similar data relating to large-scale manufacturing sector, were also compiled by the PIDE. Input structures of only those firms were obtained which employ ten persons or less.

It is interesting to compare the value added in small-scale manufacturing sector as estimated in this table will that reported in National Accounts.

Table 4

Value Added in Small-Scale Manufacturing Sector.

	(Million Rupees)
National Accounts	5,616
Present Estimates	4,755

Again, we observe a clear difference between the two sets of value-added estimates. The value added estimated in this study falls short of the value added reported in National Accounts. However, this discrepancy may be attributed to the definition we have followed to classify the small-scale manufacturing sector. National Accounts define small-scale establishments as those which employ less than twenty workers, while the census of manufacturing industries regards the firms employing even ten persons as large firms. As such, there is an overlap between small- and large-scale activities.

Consequently, only those firms were classified as small which employed ten workers or less in the present study. Obviously, the value added originating in the small-scale sectors as defined in National Accounts would be overstated as compared with that originating in small-scale activities as defined in this study due to broader coverage of the former.

### Construction

Construction has been one of the rapidly growing activities in Pakistan and as such it has an important bearing on the economy. Its exclusion from the input-output table will make the table less representative. The output originating in the construction sector flows to ownership of dwellings and the rest to investment. Since the construction activities differ in both nature of output and input structure, different types of construction activities are identified. Especially, construction in rural areas is distinguished from that in urban areas. The urban construction activities are further differentiated in low-cost buildings, luxurious buildings, factory buildings, public buildings, roads and infrastructures. As assumed in National Accounts, the value of output in construction has been taken as ten times the cost of cement and that of the value added as four times the cost of cement. The value added in rural construction is obtained by adjusting the rural value added in construction for that originating in urban sector. The value of output in rural construction as estimated in National Accounts has been taken as twice the value added in rural construction.

Data relating to urban activities have been obtained from estimates of construction in investment in various sectors which are sufficient to estimate the value of construction. On the basis of the data obtained from Nasiruddin 7137, the value of output in construction is divided into buildings and other construction. Low-cost urban buildings are also distinguished from luxurious housing. The value of output in these two activities has been estimated by dividing the value of output in residential buildings on the basis of a 75:25 ratio. This ratio was obtained from plot distributions, loan sanctions and the number of houses made up of three rooms or more as reported in the 1972 Housing Census, while the input structure has been derived from the following three sources: the Department of Urban Planning and Housing; the Nasiruddin Report 7137 and the UCL Report 7177 prepared for the Planning Commission.

#### Services

The data both on the input structures and on distribution of electricity over various sectors of the economy were obtained from WAPDA Reports. The census of electricity undertakings carried out by the Federal Bureau of Statistics also proved useful in this context. The electricity cost was distributed in accordance with the data contained in the WAPDA reports censuses of small- and large-scale manufacturing industries, and the survey of small-scale industries, while the input structure relating to electricity has been obtained from the WAPDA Report 7227.

The Sui Northern Gas Company Report provides data on both input structure and distribution of gas over various sectors. The estimates of gas use as obtained from the report were employed except in the case of the manufacturing sector, while the gas consumption estimates reported in the censuses of small- and large-scale manufacturing industries were preferred for small- and large-scale manufacturing activities.

The methodology followed in National Accounts has been pursued to estimate the value added in the wholesale and retail trade, by applying mark-ups to actual commodity production and imports. These mark-ups relate to earlier year and were also contained in previous studies on input-output tables. These old estimates were employed owing to non-availability of fresh data.

Since railways, road, air and waterways transports all differ in both output and input structure, they were separately distinguished. National Accounts provide data on output originating in all these activities. The data on input structure of air, railways and other transports were available from the Transport Cell report /22/. The report also provides data on public transport. However, the report did not provide data on private transport. A small transport survey relating to the private sector was carried out at Rawalpindi to obtain the value of output and input structure for buses and trucks.

Three communication sectors viz. Television, Radio, Telephone, Telegraph and Post have been separately distinguished as they differ both in the nature of their respective outputs

and in their input structures. Data on output and input structures for radio, telephone, telegraph and post were available from their respective Annual Reports and the profit and loss accounts, while such data on television activity were provided by the Pakistan Television Corporation.

The value of output originating in the ownership of dwellings equals the rental value of the houses. National Accounts provide data on the value of output. In order to compute the value added, the data have been adjusted for repairs and maintenance.

The value added in the government sector excludes the value added originating in telephones, telegraph and post activity. The necessary data were obtained from the Economic Analysis of the Budget 1971. Data on the value added have been obtained from the National Accounts, while the data on input structure were not available. Ultimately, we had to rely on the estimates provided in earlier input-output tables.

Table 5 compares the estimates of gross domestic product relating to National Accounts a previous version of the present input-output table and the present, revised input-output table. The GDP estimates in these two versions are lower than those given in National Accounts owing to lower value added in both small- and large-scale manufacturing sectors. Moreover the revised estimate seems slightly improved over the previous estimate. However, value-added estimates in individual sectors

corresponding to previous and revised versions of the current input-output table do not transmit any contradictory signal.

Table 5

Gross Domestic Product

(in million Rs)

Sectors	National Accounts, Estimates	Previous Estimates	Revised Estimates
1. Agriculture	38,322	39,039	39,728
a. Crop-sector	26,602	25,544	25,820
b. Non-crop sector	11,720	13,545	13,908
2. Mining and Quarrying		1,124	1,135
3. Manufacturing	20,954	19,899	19,811
a. Small-Scale	5,615	4,393	4,755
b. Large-Scale	14,433	9,506	9,056
4. Construction	6,739	6,739	6,519
5. Services n.e.s. <sup>a</sup>	54,503	55,303	55,622
Gross Domestic Product	120,586	116,154	116,815

IV. SALIENT FEATURES OF  
THE REVISED VERSION

When operating on row sums of inter-industry transaction flows, we find that the preliminary Report<sup>1</sup> on Input-output Table involved numerous problems which were not unexpected in such an ambitious exercise.

These problems relate to misallocation of a number of inputs, trade and transport mark-ups, excess of exports over output in various sectors and excess of inter-industry deliveries of different indigenous and imported products over output and imports of these goods, respectively. All such problems have together created the imbalance between supply and demand of these activities.

As regards misallocations, appropriate allocations have been made after careful scrutiny of the problem at hand. As pointed out earlier, trade and transport mark-ups also require certain readjustments. In the case of wholesale and retail trade activity, there is no consumer demand for the output originating in this sector, since the output in this activity is defined as the sum of trade margins on domestically produced and imported goods. Therefore, the existing residual of output less intermediate consumption in

1. Preliminary Report, hereinafter, refers to the PIDE Input-Output table of Pakistan's Economy by Kemal, Saleem and Tallat.

this activity has been redistributed as trade margin on both output and imports on the basis of the already existing proportions in trade margins across various activities. On the other hand, the proportion of output originating in road transport activity required to meet the consumer demand was rather too high and as such the estimates for intermediate demand in this activity seem somewhat unrealistic. In other words, the proportions of output devoted to transport margins on both output and import levels corresponding to various activities have been under-reported. To obtain reasonable estimates for transport margins on both output and import levels, the consumption coefficient relating to the earlier Input-Output Table has been employed first to estimate deliveries of the activity to consumption. The excess of the previous consumption estimate over the estimates thus obtained has been then redistributed as trade margins on output or imports on the basis of the already existing proportions in transport costs across various activities.

The output and import levels have been accordingly adjusted for these trade and transport mark-ups in order to bring them in conformity with the definition of the purchasers' price.

For a number of activities, the value of export alone has exceeded the value of output originating in

these activities, while intermediate and final demands were yet to be met from the respective output levels. This excess has been amplified manifold in some of the cases which is clearly absurd and emits an alarming signal about the reliability of the CMI data in this regard. Obviously, the CMI data drastically understate the value of output relating to these activities. One can associate this discrepancy with the price differentials that have existed between domestic and international markets for the products of these activities. No doubt, the argument seems quite plausible, yet it is not applicable in most of the cases as we do not expect any significant price differentials in domestic and international markets. In one or two cases the argument seems valid. Still the prevailing price differences in the two markets for the products of these activities do not fully compensate for the excess of export over output levels which is manifold. An indirect approach has therefore been employed to estimate the value of output in these activities. The final consumption estimates have first obtained on the basis of either the Household Income and Expenditure Survey 1972, or an earlier table by Khan and MacEwan, whichever is found appropriate to the problem in hand. The value of output in each

activity has been then obtained by summing up the final consumption thus obtained to intermediate consumption and exports relating to the respective products of these activities. The input structures relating to various activities have been adjusted for these output levels. However, these consumption estimates thus obtained cannot be regarded as true representative in the sense that the consumption output ratios relating to an earlier table assume a constant consumption pattern over time for the activities for which these ratios have been employed which is somewhat unrealistic assumption. Nevertheless, an attempt has been made to obtain somewhat reasonable estimates of output levels for the activities in question in the absence of independent information on final consumption of these products.

The inter-industry consumption estimates of various inputs as reported in the preliminary report have exceeded their respective output levels for a number of activities. The excess can be attributed partially to indirect imports and partially to the consumption of previous stocks. Although the CMI reports data on direct imports, it does not report data on indirect imports. Since the imports, made by various activities both for their own consumption and for meeting the inter-industry demand of various other activities are,

when retransferred, considered domestic deliveries to various sectors of the economy, they may result in overstating the inter-industry consumption of domestically produced goods and in understating the intermediate consumption of imported goods. As a result, such problems have been observed for a number of activities in the preliminary report of the input-output table. Again, due to non-availability of independent information on final consumption of indigenous or imported goods, we have to rely on the Household Income and Expenditure Survey or on Khan and MacEwan's Table to obtain indirect estimates of consumer demand. However, this estimation procedure has its own limitations a constant consumption pattern for both imported and domestically produced goods has been assumed which is not very realistic. Nevertheless, no other option is available. These consumption estimates for domestically produced goods, coupled with exports, have been employed to arrive at the intermediate demand for the products of the activities in question. The excess of the previous inter-industry consumption estimates over the estimates thus obtained for various activities have been allocated to the intermediate consumption of respective imported goods, provided the imports allow for it. The residual has been allocated to stock changes and the corresponding row adjustments both for indigenous and imported inputs have been then made.

Still another problem of vital concern is that small-scale activities do not distinguish between indigenous and imported inputs and as such indigenous inputs have been lumped with the imported inputs in these activities. In order to resolve this problem, corresponding to each activity in the small-scale manufacturing sector, an activity in the large-scale manufacturing sector has been first identified. The proportions of 'imported inputs' in the total for various large-scale activities have been then applied to the corresponding inputs in each small-scale activity as to obtain a separate account for imported inputs. These proportions implicitly assume the small-scale activities to be as import-intensive as large-scale activities are. It has been further assumed that small-scale activities conduct purchases of the imported inputs only to meet their own requirements and do not sell out these inputs to other activities. That is to say, small-scale activities fulfill their import requirements through purchases of these inputs from the large-scale manufacturing sector alone.

In the process of revising the table, a number of activities have been re-estimated. Petroleum Products and infrastructures have been estimated on altogether fresh data.

all these innovations and adjustments have changed the whole texture of the preliminary report. Most importantly, the basic accounting framework has been altogether changed in the revised version wherein tow sets of accounting equations, one for

domestically produced goods and the other for imported goods, have been identified to estimate various inter-industry relations in the economy.

#### Final Demand

There are, in fact, two final demand vectors corresponding to two different sets of accounting equations, one for indigenous and the other for imported goods. The final demand for domestically produced goods may be defined as comprising of consumptions investment, stock change and exports, while the final demand for imported goods may be regarded as consisting of consumption, investment, stock changes and re-exports. Basically, the final demand for indigenous/imported goods is nothing more than the distribution of the difference between output/import levels and the intermediate demand for these goods among consumption, investment, stock changes and exports/re-exports. Since there is no direct information available on various components of the final demand, except on exports and re-exports for which data are available from independent sources, these have been arrived at by using the residual method.

When exports are subtracted from their respective residuals of output less intermediate demand for products of various activities, we are left with a remainder which consists of consumption, investment and stock changes. Likewise, we can arrive at a similar final demand residual for imported goods.

Stock changes in both indigenous or imported activities have been identified separately when a residual could not be explained other than a stock change and, as such most of the commodity deliveries (indigenous or imported) to consumption and investment include an element of stock change.

The residuals of the final demand for both indigenous and imported goods are still to be distinguished between the deliveries to consumption and investment. The residuals appearing against all the construction activities have been directly allocated to investment. In order to distinguish the residuals by consumption and investment, the goods both indigenous and imported which are likely to be invested, have been identified in the first instance. On the other hand, the proportions of output levels relating to these goods in total have been applied to their respective residuals in order to arrive at investment estimates of these activities. The residuals net of these investment estimates corresponding to various activities have been allocated to consumption.

V. LIMITATIONS OF THE STUDY AND DIRECTION OF FURTHER RESEARCH

Pakistan, being a developing economy, is no exception regarding data availability constraints which always cause injury to researcher's zeal in pursuing perfection in his goals. Given a strong data base, a researcher enjoys a fair amount of confidence in suggesting various policy measures based on his research exercises in different spheres of the economy which may otherwise prove fatal or misleading. The situation becomes even worse when one is dealing with economy-wide accounting exercise such as input-output tables which involve enormous data. And where in any inconsistency left not only affects the quality of the table itself, it also affects by an amplified magnitude the quality of the table-based exercises which vary from multi-sectoral modelling to evaluating the consistency, feasibility and optimality of various economic plans.

This perception in no way suggests that such exercises in the absence of strong data base are useless. Yet it is not advisable to work under these conditions all the time. Almost every research exercise ends up in exploring certain data gaps or in accruing dis-satisfaction over the quality of the existing data which always define their own limits to a given exercise. These data gaps or data which are of poor quality must be brought to the notice of the data-producing agencies.

Unfortunately, in Pakistan the co-ordination system between researchers, planners and data producing agencies, if at all

existing is quite loosely organized. This lack of co-ordination in data has left the problem of data availability or consistency unresolved. Hence, there is an imminent need for pooling the work effort of these agencies so as to provide a data base of reasonably good quality relating to those areas of the economy in which data are either insufficient or altogether missing.

In this spirit, an economy-wide input-output table exercise was initiated by the PIDE. It also aimed at exploring the various existing data gaps which have limited the scope of the study to a certain extent. Data gaps, which have been brought under sharp focus in this study, relate almost to all sectors of the economy and require some serious attention from the data-producing agencies. Next, we will try to elaborate the humps and valleys of data that we have come across in the present study.

While the National Accounts provide data on the value of agriculture output, they do not provide data on inputs in agriculture. On the other hand, the Census of Agriculture does not report data on value of output though it does report data on some of the inputs. In this study, the relevant information has been gathered from both National Accounts and a VAPDA Survey report to estimate input-output co-efficients in the agriculture sector. There is an imminent need for a comprehensive survey of the agriculture sector. It may be noted that the existing data have failed to distinguish a number of agricultural

activities, viz. fruits, vegetables, spices, fodder and other minor crops, which have an important bearing on the growth and prospects of agriculture. Similarly, the data on growing of tobacco, pulses, oilseeds and other crops were insufficient to distinguish small- and large-farm activities. In any future attempt at input-output tables, small- and large-farm activities should also be distinguished. Moreover, the data required for the valuation of fodder have been rather insufficient and the estimates included here are based on a small survey and some adhoc assumptions. Finally, data on primary inputs employed in agriculture have been altogether nonexistent. The need for a detailed survey in this direction is quite obvious.

The value of output originating in livestock has been estimated as described in National Accounts, i.e. a constant animal/bird ratio is assumed. These ratios relate to the early Sixties and even at that time they were mere educated guesses. Therefore, the livestock census which is periodically carried out in Pakistan should include value of output in addition to the head-count. Moreover a comprehensive survey is essential to estimate the cost of maintaining animals. The studies which have so far been carried out in this context are based on very small samples.

National Accounts grossly underestimate the value of output originating in the forestry only because the wood cut in rural areas has not been taken care of. Since it forms a major proportion of forest activity, the omission is quite conspicuous.

The need of a survey is evident.

While the data on the value of output in mining seem of good quality, they miss out the quarrying activities, viz. sand and stone used in the construction activities. In the present study, the National Accounts data have been adjusted for the input use in the construction sector.

Data on small- and large-scale manufacturing industries were sufficient to distinguish a reasonable level of sectoral disaggregation. However, the quality of data, especially of those relating to other costs, needs to be significantly improved. The cost structures relating to small-scale activities do not distinguish between indigenous and imported inputs which should be accounted for in future surveys of small-scale industries. Moreover, the National Accounts data do not account for the small-scale activities existing in rural areas, which in fact stresses the need for a survey.

Although seven different activities have been distinguished in the construction sector, yet we have been forced to rely on secondary data sources. One feels that there is a need to conduct an extensive survey of the construction sector. The cost structure relating to these activities must also distinguish between indigenous and imported inputs and should account for primary inputs and taxes and/or subsidies.

As regards services, data were sufficient and of good quality in most of the activities in this sector, such as

electricity; gas; banking and insurance; rail; air and water transport; government; television; radio; telephone, post and telegraph. However, in the cases of ownership of dwellings, road transport, wholesale and retail trade and other services, data for more recent year were not available. Since these are important activities, the need for surveys of such activities is obvious.

Last but not the least is the final demand which may be defined as comprising consumption, investment, stock changes and exports. basically, final demand is not more than distribution of the difference between total availability and intermediate demand among consumption, investment, stock changes, and exports. However, the independent information on these components of the final demand is very useful in evaluating the consistency of the input-output tables. The absence not only makes the residual distribution arbitrary, it also leaves the consistency of the table quite doubtful. The sector-wise non-availability of the information on these components has been an over-emphasized problem in Pakistan. Efforts in this direction must be accelerated without any further delay in order to provide better conditions for accounting exercises. Data on exports of various products are of reasonably good quality and quite in line with sectoral disaggregation. But such data on consumption, investment and stock changes are hardly available. In the present study, these components have been arrived at through residual method. Therefore, there is an obvious need for conducting surveys to cover these important final demand components at least after every five years, if not annually.

It would be more appropriate to relate these surveys to the years in which the census of manufacturing industries takes place.

Finally, since input-output co-efficients do change over time, even if gradually, they lose much of their utility unless tables are prepared quite regularly. However, preparation of input-output tables on an annual basis has to be ruled out as they involve enormous data and manpower. Nevertheless, such tables may be formulated after every five years and coefficients adjusted for the intervening period with the use of the well-known RAS Method.
